Record Nr. UNINA9910557748703321 Autore Carrasco Gary Titolo Biocomposite Inks for 3D Printing Basel, Switzerland, : MDPI - Multidisciplinary Digital Publishing Pubbl/distr/stampa Institute, 2021 1 online resource (213 p.) Descrizione fisica Soggetti Information technology industries Lingua di pubblicazione Inglese **Formato** Materiale a stampa Livello bibliografico Monografia Three-dimensional (3D) printing has evolved massively during the last Sommario/riassunto years. The 3D printing technologies offer various advantages. including: i) tailor-made design, ii) rapid prototyping, and iii) manufacturing of complex structures. Importantly, 3D printing is currently finding its potential in tissue engineering, wound dressings, tissue models for drug testing, prosthesis, and biosensors, to name a few. One important factor is the optimized composition of inks that can facilitate the deposition of cells, fabrication of vascularized tissue and the structuring of complex constructs that are similar to functional organs. Biocomposite inks can include synthetic and natural polymers, such as poly (-caprolactone), polylactic acid, collagen, hyaluronic acid, alginate, nanocellulose, and may be complemented with cross-linkers to stabilize the constructs and with bioactive molecules to add functionality. Inks that contain living cells are referred to as bioinks and the process as 3D bioprinting. Some of the key aspects of the formulation of bioinks are, e.g., the tailoring of mechanical properties. biocompatibility and the rheological behavior of the ink which may affect the cell viability, proliferation, and cell differentiation. The current

Special Issue emphasizes the bio-technological engineering of novel

considering important aspects in the production and use of bioinks.

biocomposite inks for various 3D printing technologies, also
