| Sommario/riassunto      | Conventional pharmaceutical approaches to pain management are not  |

always successful. Using only those medications that have an official indication for a certain condition reduces substantially the chance of the patient gaining pain relief and may expose them to intolerable side effects. However evidence now exists on the use of other drugs, produced for non-pain conditions, and how they can substantially increase the chances of pain relief. Covering the most recent developments in this field, McCleane offers an alternative solution to pain treatment when conventional treatments fail.

Sommario/riassunto

By two years of age, healthy infants in the United States can receive up to 20 vaccinations to protect against 11 diseases. Although most people know that vaccines effectively protect against serious infectious diseases, approximately one-quarter of parents in a recent survey believe that infants get more vaccines than are good for them, and that too many immunizations could overwhelm an infant's immune system. The Immunization Safety Review Committee reviewed the evidence regarding the hypothesis that multiple immunizations increase the risk for immune dysfunction. Specifically, the committee looked at evidence of potential biological mechanisms and at epidemiological evidence for or against causality related to risk for infections, the autoimmune disease type 1 diabetes, and allergic disorders.
